Patent Office  
Canberra

I, LEANNE MYNOTT, MANAGER EXAMINATION SUPPORT AND SALES hereby certify that annexed is a true copy of the Provisional specification in connection with Application No. 2004900118 for a patent by SECURENCY PTY LIMITED as filed on 09 January 2004.

WITNESS my hand this  
Twentieth day of January 2005

A handwritten signature in dark ink, appearing to be 'LA'.

## **PROVISIONAL SPECIFICATION**

**Invention Title:        Method and apparatus for inspection of security articles**

**The invention is described in the following statement:**

## METHOD AND APPARATUS FOR INSPECTION OF SECURITY ARTICLES

This invention relates to security articles, such as banknotes or other security documents, and is particularly concerned with providing a method and an apparatus  
5 for inspecting a security device or devices in one or more security articles.

As used herein, the term "security documents" includes documents and tokens such as identity documents, value documents or entrance documents, which in turn respectively include: passports, visas, identity cards, drivers licences, and security entrance cards, banknotes, shares, bonds, certificates, cheques, lottery  
10 tickets, bank cards, charge cards and credit cards, and aeroplane tickets, bus tickets, railroad tickets, and tickets to fun parks or specific rides. These security documents or tokens typically include some form of authenticity verification to guard against copying and fraudulent alteration. It will, however, be appreciated that this invention is applicable to other types of articles which require authentication and/or  
15 protection against copying or theft. Such articles, including security documents, are referred to broadly as "security articles" in this specification.

A wide variety of security devices have been proposed for use in security documents for verification of authenticity and to make counterfeiting of the documents difficult. Some types of security devices are low security devices, e.g.  
20 printed devices or embossings, which are relatively inexpensive to produce in security documents but which only provide a relatively low degree of security. Other types of security devices are high security devices, such as diffraction gratings or holograms. These can provide a higher degree of security because they are more difficult to counterfeit, but are more expensive to produce and so are  
25 generally used in higher value security documents, such as \$50 or \$100 banknotes.

When high security devices are provided in banknotes, it is desirable to detect their presence and quality in the production process of the banknotes before the banknotes are issued to the public. It is also desirable to provide apparatus for inspecting a high security device in a single banknote.

30 WO 99/37488 discloses a security document and method in which a

diffraction optical projection element is provided within a transparent portion or window in the document. The diffraction optical projection element transforms a collimated beam of light, e.g. from a point light source or laser, into a patterned beam of a selected design. In the method of verifying the authenticity of the security document described in WO 99/37488, the patterned beam is projected onto a viewing surface, e.g. by folding the security document so that another part of the document laterally spaced from the window acts as the viewing surface. In another embodiment, the security document of WO 99/37488 may include a second transparent portion or window which can act as a pseudo point light source when the security document is folded.

In each embodiment described in WO 99/37488, the authenticity of the security document incorporating the diffraction optical projection element is verified visually by a person viewing the patterned beam when it impinges upon a viewing surface. However, this visual viewing method is not very suitable for inspecting the presence or quality of diffraction optical elements in banknotes or sheets of banknotes in equipment such as printing equipment, note sorting equipment or other equipment used in processing banknotes or the like.

According to one aspect of the invention, there is provided a method for inspection of at least one security article, wherein the security article incorporates a diffraction optical projection element as a security device, and wherein the method comprises the steps of:

directing a beam of light from a light source onto said diffraction optical projection element so that the diffraction optical projection element produces a patterned beam of light, which forms a projected image; and  
detecting the projected image with an optical detection device located at a position at which the patterned beam of light is reconstructed to form the projected image.

According to a second aspect of the invention, there is provided an apparatus for inspection of at least one security article incorporating a diffraction optical projection element as a security device, wherein the apparatus comprises:

a light source for directing a beam of light onto said diffractive optical projection element whereby the diffractive optical projection element produces a patterned beam of light which forms a projected image; and

5 detection means in the form of an optical detection device located at a position at which the patterned beam of light is reconstructed to form the projected image.

The light source is preferably arranged to direct a substantially collimated beam of light onto the diffractive optical projection element. The light source is preferably a point light source, such as a light emitting diode (LED), a halogen light source or a laser (solid state or otherwise). It will, however, be appreciated that  
10 other types of point light sources may be used.

The optical device forming the detection means for detecting the projected image is preferably arranged to detect the amplitude of different parts of the patterned light beam forming the projected image. The detection means may  
15 comprise one or more photodiodes, e.g. an array of photodiodes, or a charge couple device (CCD), such as a line CCD or a matrix CCD.

In one preferred embodiment, the diffractive optical projection element is provided in a substantially transparent or translucent portion or window in a security document, the light source is positioned on one side of the security  
20 document and the detection means is positioned on the opposite side of the security document. Thus light passes through the diffractive optical projection element and the incident light beam is transformed into the patterned beam on the opposite side of the document and projected onto the detection means.

In an alternative embodiment, the diffractive optical projection element may  
25 overlie a reflective surface, such as a metallic layer or coating of the security article. In this case, the light source and the detection means may be provided on the same side of the security article with the incident beam being reflected back from the reflective surface through the diffractive optical projection element when it is transformed into the patterned beam and projected onto the detection means.

30 In accordance with the invention the apparatus may be incorporated into a

wide variety of equipment for printing, sorting, counting, handling or otherwise processing security documents. For example, a light source and associated detection means may be provided for inspecting individual banknotes in a note counter or note sorter. The apparatus may include a plurality of optical detection  
5 devices, for instance when a sheet containing a plurality of banknotes each containing diffractive optical projection elements is required to be inspected, e.g. during the printing of a sheet of banknotes.

According to a third aspect of the invention there is provided equipment for sorting, handling or otherwise processing security articles comprising inspection  
10 apparatus in accordance with the second aspect of the invention and processing means for subsequently processing the security articles according to signals received from the detection means. For example, if the detection means identifies a faulty security article, it may emit a signal rejecting the faulty article so that the article can be marked for rejection and/or rejected from the security article  
15 processing equipment.

According to a fourth aspect of the invention, there is provided a method of processing or handling security articles comprising a method for inspection in accordance with the first aspect of the invention, wherein a signal is generated by the optical device when it detects the absence or poor quality of a diffractive optical  
20 projection element in a security article, and isolating or marking the security article.

In a further embodiment, a plurality of light sources may be provided for illuminating at least one diffractive optical projection element. Each of the light sources may cause a patterned beam to be diffracted at a slightly different point on the optical detection device, creating multiple signals on the same detector. By  
25 integrating these signals and sampling the signal over a period of time, it is possible to differentiate constructive diffraction produced by the diffractive optical projection element from a random or diffuse scattering of light, such as that caused by a scratch or a surface imperfection, or light transmitted through a standard diffraction grating or hologram.

30 It is also envisaged that a moving light source which produces an incident

light beam that scans across the diffractive optical projection element could be used to create multiple signals at the optical detector.

Preferred embodiments of the present invention will now be described, by way of example only, with reference to the accompanying drawings, in which:

5      Figure 1 is a schematic drawing of apparatus for inspecting a security document incorporating a diffractive optical projection element;

Figure 2 is a schematic drawing of apparatus for inspecting a modified security document;

10      Figure 3 is a block diagram of sorting equipment incorporating the inspection apparatus of Figure 1 or Figure 2; and

Figure 4 is a schematic flow chart of a method of sorting documents using the equipment of Figure 3.

15      Figure 1 shows apparatus for inspection of a security document 10 incorporating a diffractive optical projection element (DOE) 11 provided in a transparent portion or window 12 of the document 10. The apparatus comprises a point light source 14 which directs an incident beam of substantially collimated light 15 onto the DOE 11, and detection means in the form of an optical detection device 16.

20      In one preferred embodiment, the security document 10 may be formed from an at least partially transparent substrate having one or more opacifying layers or coatings applied to at least one face of the substrate. The transparent portion or window 12 of the security document 10 may be formed by applying the opacifying layers or coatings to the substrate in such a manner that the substrate 12 is substantially free of opacifying layers or coatings in the region of the transparent portion or window 12. The transparent substrate may be formed from a transparent polymeric material, such as polyethylene (PE), polypropylene (PP) or polyethylene terephthalate (PET). In the case of a banknote, the substrate is preferably formed from at least one biaxially oriented polymeric film. The substrate may comprise a single film of polymeric material. Alternatively, the substrate may comprise a  
30      laminate of two or more layers of transparent biaxially oriented polymeric film.

It will, however, be appreciated that the present invention is equally applicable to security documents formed from paper or other partially or fully opaque material. In this case, an aperture may be formed in the paper or other material and a patch of transparent polymeric material inserted into or applied over the aperture to form the transparent portion or window 12.

The opacifying layers may comprise one or more of a variety of opacifying inks which can be used in the printing of banknotes or other security documents. For example, the layers of opacifying ink may comprise pigmented coatings comprising a pigment, such as titanium dioxide, dispersed within a binder or carrier of cross-linkable polymeric material.

The diffractive optical projection element 11 acts to transform the incident light beam 15 from the point light source 14 as the beam passes through the at least partially transparent portion 12 of the security document (the window created through the security document) into a patterned beam 17 of selected design. The diffractive optical projection element is of the type which acts to generate the patterned beam 17 by diffraction of the light beam 10. One example of such a device is a diffractive optic projection element or diffuser made by Mems Optical, Inc. in accordance with WO 98/32590. Such devices are complicated surface microrelief structures similar to diffraction gratings. Whilst the optical transformation of the incident light beam 15 to the patterned beam 17 is based on the optical principle of diffraction, the mathematics of the structure of such devices is specifically designed in each case to produce a distinct optical transformation in order to produce a desired patterned image at a particular point in space away from the security document 10. Each diffractive optic projection element 11 can be dependent on the wavelength of the light beam used.

The point light source 14 for producing the incident beam 15 may comprise an LED, a halogen light source, a laser or other light source for producing a beam of substantially collimated light which is directed on the DOE 11.

The optical detection device 16 is positioned at the particular point in space at which the patterned beam 17 forms the patterned image projected by the DOE 11.

The various points in space of the image projected by the DOE 11 are determined by the special focal coordinates created by a sinusoidal grating which constitutes the DOE 11 and the positions of the light source 14 and detector 16 relative to the DOE 11.

5       The presence of the patterned image projected by the DOE 11 is determined by the amplitude of the response of the detector 16 at particular points in space where the detector is located. For this purpose, the detector may comprise an array of photo-diodes 18, or a charge couple device (CCD) such as a line CCD or a matrix CCD.

10       Figure 2 shows a modified embodiment which is similar to Figure 1 and corresponding reference numerals have been applied to corresponding parts. The security document 20 in Figure 2 differs from that of Figure 1 in that the transparent portion or window 12 incorporates a reflective surface 21 underneath the diffractive optical projection element (DOE) 11. The reflective surface may be provided by a  
15       metallic layer 22 provided within the window 12 or by a metallised coating applied to a surface of the transparent portion forming the window 12 before the DOE 11 is applied over the reflective surface 21.

      The apparatus of Figure 2 also differs from that of Figure 1 insofar as the point light source 24 and the optical detector 26 are located on the same side of the  
20       security document 20. The light source 24 is arranged to direct a substantially collimated incident beam 15 onto the window 12 at an acute angle to the perpendicular to the surface of the security document 20 so that the incident beam 15 is reflected back from the reflective surface 21 of the metallic layer 22 onto the DOE 11. The reflected beam passes through the DOE 11 and is transformed by the  
25       DOE 11 into a patterned beam 17 in similar manner to the embodiment of Figure 1.

      The detector 26, which may also comprise an array of photo-diodes 18 or a line or matrix CCD, is disposed at a position relative to the security document 20 to receive the patterned beam 17 which also travels from the DOE 11 at an acute angle to the perpendicular to the surface of the security document 20 corresponding to the  
30       angle of the incident beam 16. Otherwise, the detector 26 functions in exactly the

same manner as the detector of Figure 1 by determining the amplitude of different parts of projected image formed by the patterned beam 17 at particular points in space where the photo-diodes 18 are located.

Figures 3 and 4 illustrate sorting equipment and a method of sorting security documents utilizing the inspection apparatus of Figure 1 or Figure 2.

The sorting equipment of Figure 3 comprises an edge detector 30 for detecting the presence of a security document, such as a banknote, or a sheet of banknotes, a window locator 32 for locating a window 12 in a security document incorporating a DOE 11, an optical detector 16, 26 in the form of a CCD or photo-diode array for inspecting a patterned beam 17 from the DOE 11, a processor 34 for processing and analysing signals from the optical detector 16, 26, a barcode printer 36 and a document sorter 38 for sorting the security documents according to the signals from the optical detector 16, 26.

The method of operation of the sorting equipment of Figure 3 is illustrated by the flow chart of Figure 4. When a security document, e.g. a banknote, or a sheet of banknotes enters the sorting equipment, the edge detector 30 detects the presence of a banknote, or a sheet of notes, by detecting the edge of the note or sheet (Step 40). When the window locator 32 locates a window in the note or sheet (Step 42), e.g. by means of a time gated output from the processor 34, the light source (14, 24) and the CCD or photodiodes of the optical detector 16, 26 of the inspection apparatus are activated (Step 44).

The optical detector 16, 26 then performs its inspection of the security document and produces output signals that are input to the processor 34 which analyses the signals (Step 46). The processor 34 may comprise a process logic controller (PLC) or a microprocessor, such as a PIC chip, and can not only determine whether a DOE 11 is present in the window of the document, but can also determine the quality of the DOE by its inspection of the projected image formed by the patterned beam 17 from the DOE.

From its signal analysis, the processor (PLC) 34 determines whether or not the banknote should be accepted or rejected (Step 48), and outputs either an accept

signal (Step 50) or a reject signal (Step 52). The output signals from the processor 34 are input to the barcode printer 36 which prints either an accept code (Step 54) or a reject code (Step 56) on the banknote or sheet of banknotes. The banknote or sheet of banknotes are then fed to the sorter 38 which sorts the documents (Step 58) by sending those marked with an accept code (54) to a delivery stack and by sending those marked with a reject code (56) to a reject stack.

The method and apparatus of the present invention therefore provides an efficient way of automatically inspecting security articles, such as banknotes, which incorporate diffractive optical projection elements (DOEs) as high security devices. The inspection method and apparatus may be used in a wide variety of equipment, such as printing equipment, note counting or sorting equipment or any other equipment used in the printing, handling or processing of security documents or other security articles.

It will be appreciated that various modifications and alterations may be made to the embodiments described above without departing from the cope and spirit of the present invention. For example, the inspection apparatus of Figures 1 or 2 may be used to inspect other types of security articles having either a DOE provided in a transparent portion or window or a DOE provided on a reflective surface of the security article.
